## I. Overview

The FMod-I2C5LedDriver SLP 58/0.5 is a very small control device for LEDs lightning. It is particularly interesting because of its small size, the quality of its regulation and the power that can be delivered (up to 140 W continuous).

The driver receives consigs, thanks to its I2C bus, to regulate the 5 different currents of its 5 LEDs outputs. For each output, the user specifies an independent goal current and a speed at which the driver will get to the goal. This allows the user to have a full control of a lighting system, easily configurable and with an automatic ultra-low power mode when all the LEDs are switched-off. In standby and at ambient temperature, the device consumption is maximum of 50nA on logic 5V and 100nA on power supply.

This SLP daughter board (“SLP” stands for Soldered Low Power) can easily be soldered directly to a motherboard without any cables through its 32 + 2 plated holes on board edge (1.27mm spacing). In addition to that, 1.27 mm spacing male connector can be soldered to the board, making it plugable, horizontally or vertically, to a dedicated motherboard.

Up to 112 devices can be connected to the same I2C bus in daisychain configuration. Access through I<sup>2</sup>C can be made by the user or with the help of another FiveCo device, FMod-TCP DB or FMod-TCP Box 2 which are bridges between TCP/IP and I<sup>2</sup>C. Refer to the chapter “*I2C Interface*” to have more information on how to communicate with the board.

## 2. Hardware Specifications

### Operating conditions

LED power	
Supply voltage	9 - 58 VDC
Supply current <sup>1</sup>	2.6 A max ( $\Sigma$ LED channel currents + 100mA)
Logic power	
Supply voltage	5 VDC
Supply current <sup>2</sup> ( <i>OPTIONS.0</i> = 0) ( <i>OPTIONS.0</i> = 1)	10 mA max 5 mA max
Standby consumption	
Logic current	< 50 nA @5V, 25°C
Power current	< 100nA @58V, 25°C
Input/Output	
Inputs for general purpose	5 A/D (5V)
Output LED channels	5 (LED1, LED2, LED3, LED4, LED5)
Output LED voltage (each channel)	< (LED power supply voltage -2V)
Output LED current (each channel)	10-500mA $\pm$ 5mA
Other	
LED driver switching frequency	600 kHz

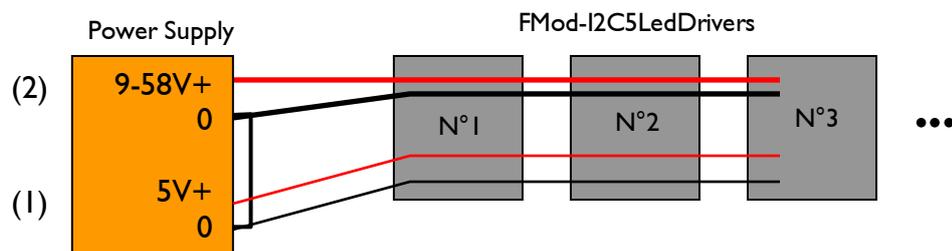

<sup>1</sup> Consumption (LED Power 9-58V) of driver electronics when all output LED channels are enable :  
< 12 mA @12 V  
< 31 mA @58 V

<sup>2</sup> Consumption (logic power 5V) when no load is connected to the ADEN pins

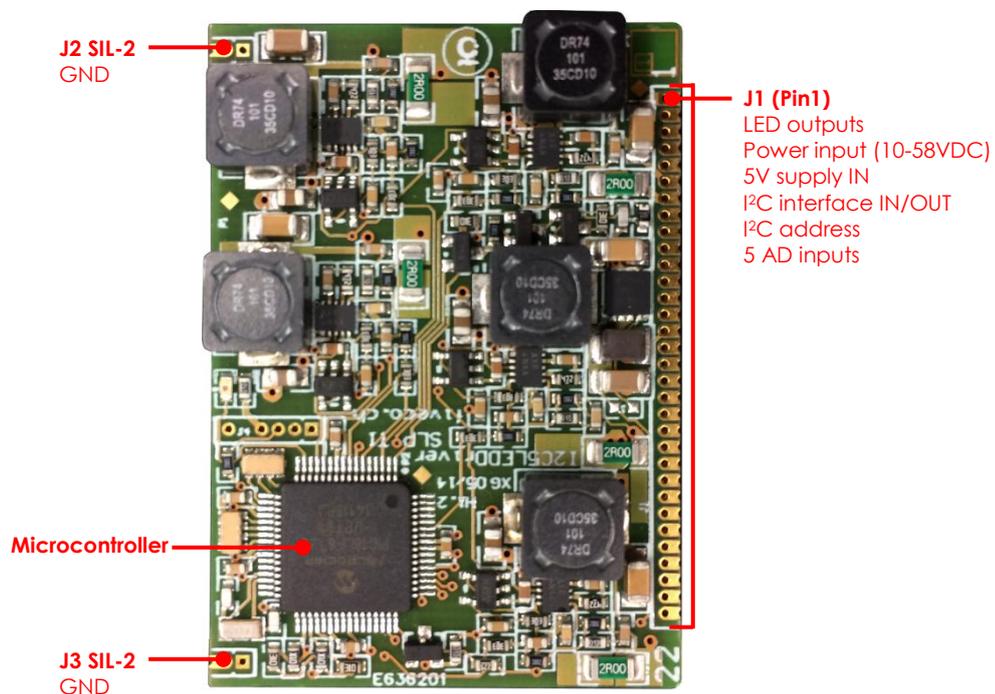

## Power supply

1. Logic power: VCC (+5V) used for the electronics and processor must be applied on the Logic 5Vpins. (See details on section “Pin description”)
2. LEDs power 9-58 V with the peak current minimal of  $\sum$  LED channel currents + 100mA (2.6 A max) must be applied on the LEDs power pins.

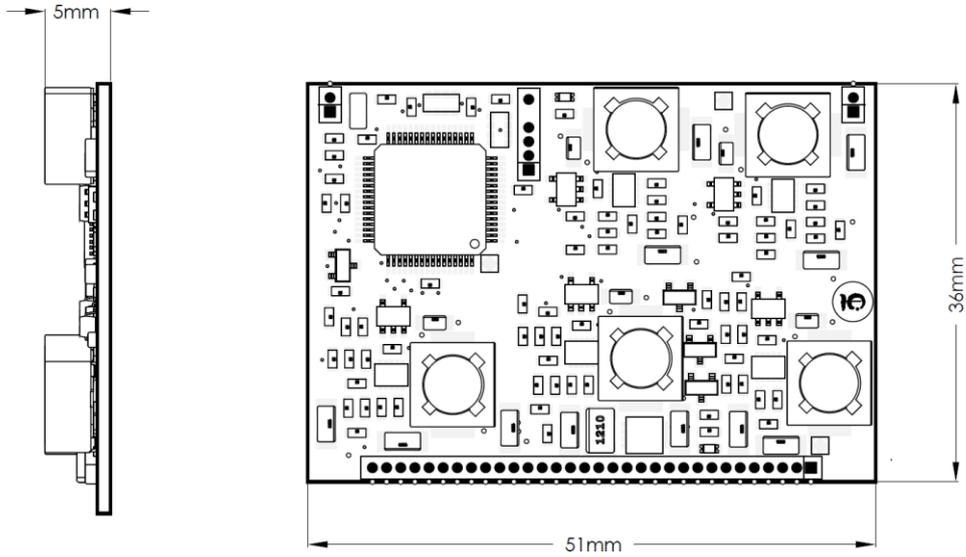

!!! Both power supplies must be connected to the same ground. !!!

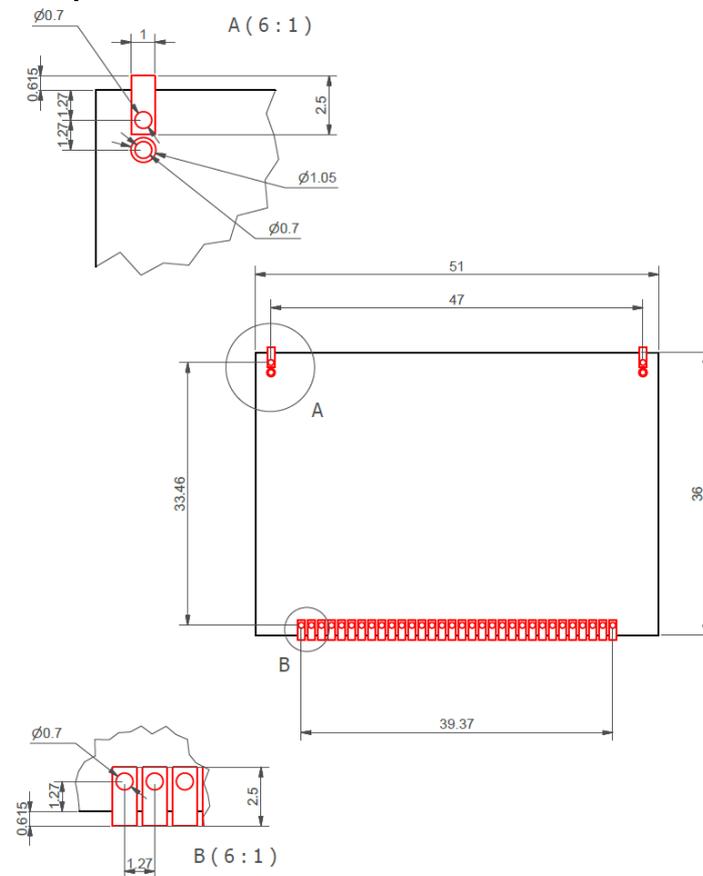

## Hardware description

**Physical Dimensions [mm]**

**Footprint**

Holes ( $\phi 0.7$ ) are optional and only needed if you want to use 1.27mm inline pin connectors.

**Pin description**

CONNECTOR J1				
PIN	Function		PIN	Function
1	GND (0V)		17	I <sup>2</sup> C-SCL
2	LED5 +		18	I <sup>2</sup> C-SDA
3	LED5 –		19	I <sup>2</sup> C-Add0
4	LED4 +		20	I <sup>2</sup> C-Add1
5	LED4 –		21	I <sup>2</sup> C-Add2
6	LED3 +		22	I <sup>2</sup> C-Add3
7	LED3 –		23	I <sup>2</sup> C-Add4
8	LED2 +		24	I <sup>2</sup> C-Add5
9	LED2 –		25	I <sup>2</sup> C-Add6
10	LED1 +		26	AD1
11	LED1 –		27	AD2
12	PWR (10-58VDC)		28	AD3
13	PWR (10-58VDC)		29	AD4
14	GND (0V)		30	AD5
15	GND (0V)		31	ADEN (out)
16	+5V0 (in)		32	GND (0V)

**Notes:**

- The device's logic power supply (electronics and processor) is on pin 16 (Logic +5V) and must be applied externally. A second power supply (+9-58V) for the LEDs must be connected to pins 12 and 13.
- All GND pins must be connected together (ideally to a ground plan) on the mother board.
- The power supply for A/D inputs (ADEN) is on pin 31 and is off in ultra-low power mode allowing power saving. So, electronics used to produce AD signal is automatically shutdown when AD that are powered by ADEN are unused.

**Warning**

During the installation process, it is important to make sure that the output lines are not crossed (example: a LED being plugged to LED1+ and LED2-). This could permanently damage the LEDs as well as the module itself.

Under 5.5 V on PWR pins, the driver is automatically switched off.

### 3. Detailed description

#### Overall system

The FMod-I2C5LedDriver SLP 58/0.5 is composed of a microcontroller, 5 LED driver modules, a temperature sensor and a voltage sensor. Commands and settings are sent to the microprocessor through the I<sup>2</sup>C interface. The microcontroller processes the data and generates endpoints (in the form of a PWM) for the 5 independent LED driver modules. These will drive LED outputs in order to achieve the desired LED currents.

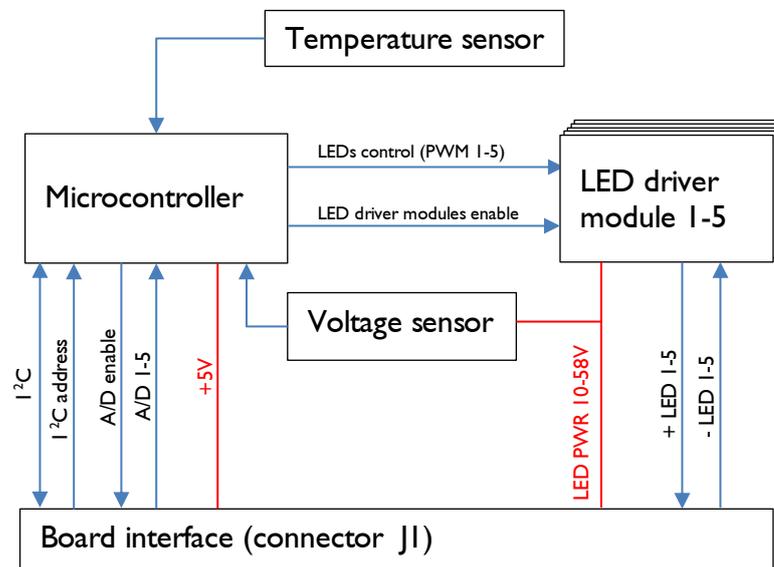

Figure 1 - Bloc diagram of the FMod-I2C5LedDriver SLP

#### Typical application

Each of the 5 LED outputs drives up to 500mA. The current can be distributed in several branches of LEDs. In this case, an additional resistor is mandatory on each branch to get a proper distribution of the current. The number of LEDs per branch is limited by the maximal forward voltage of the LED (this value is usually found on datasheets of the LEDs) and the maximal LED driver output voltage (LED driver input power – 2V). The ADEN pin can power analogic system (potentiometer, switch, sensor,...) at 5V and 24mA max. Acquisition is done independently on each AD inputs.

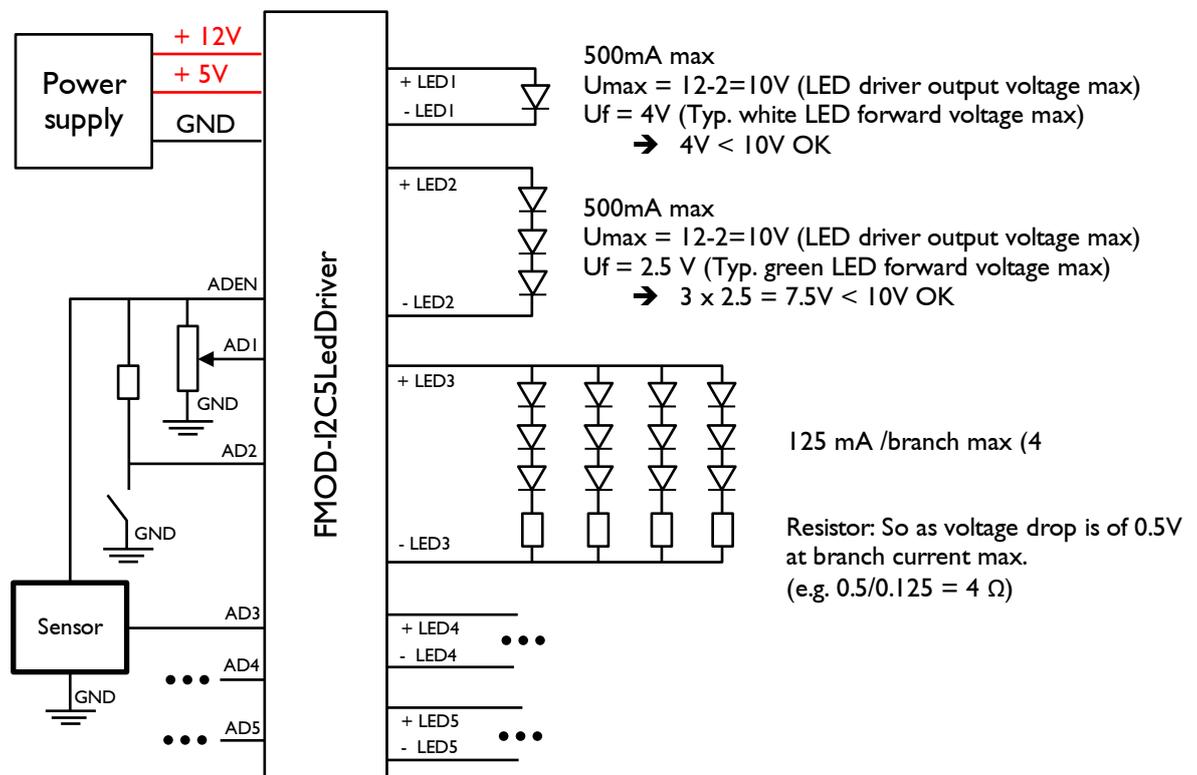

Figure 2 - Typical application of the FMod-I2C5LedDriver SLP.

## How to use the driver?

The LED driver is very easy to use since it needs only two steps to work.

1. Configure settings for the current application.
2. Send commands to the driver.
- (3.) Monitor the driver.

Settings can be saved so as they are automatically restored when the driver reboots (e.g. if power is cut off). Moreover, the driver will automatically goes in low power mode when all LEDs are turned off.

### I. Configure settings for the current application

1. First, write in DRVVOLTAGEMIN the minimal input voltage above which the driver will operate. If you don't mind about this parameter, you can leave the default value: 0x00058000 (5.5V).
2. Then, the maximal LED output current has to be defined for each output. For example, if the maximal current must not exceed 40mA on the LED2 output, write 0x0A3D in LED2CURRENTMAX. ( $0.04 \times 65'536 = 2621.44 = 0x0A3D$ ).

3. Finally, you can save settings thanks to the `SAVEUSERPARAMETERS` function. Once it is done, settings will automatically be restored at startup. (See Section 5 for more detail)

## 2. Send commands to the driver

Now you can start to use the driver by sending I2C commands.

### Example

If you want to create a smooth oscillation of light on LED2 output (as described in Figure 3) you have to follow the sequence shown in Table I.

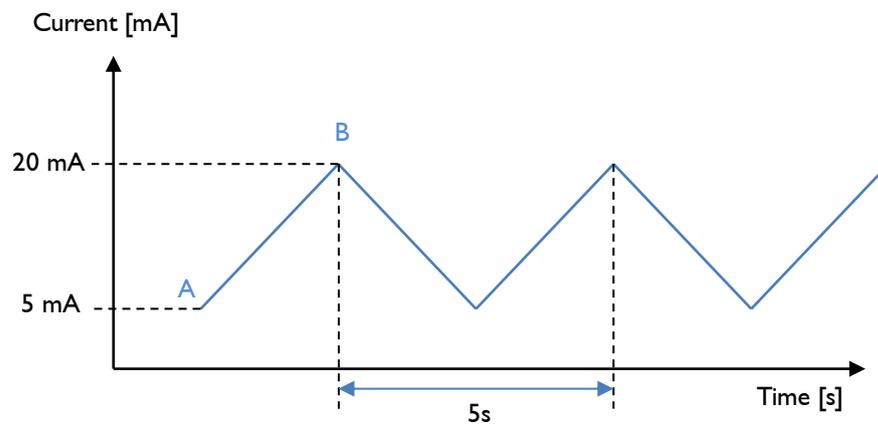

Figure 3 - LED oscillation example.

STEP	ACTION
1 <sup>3</sup>	Write 0x2000FFFF in <code>LED2GOAL</code>
2	Write 0x8000000A in <code>LED2GOAL</code>
3	Wait 2.5 s
4	Write 0x2000000A in <code>LED2GOAL</code>
5	Wait 2.5 s
6	Write 0x8000000A in <code>LED2GOAL</code>
...	...

Table I – LED oscillation sequence example (`LED2CURRENTMAX = 0x0A3D`).

<sup>3</sup> This command makes sur that the sequence starts at the good point. Whitout it, you could have a problem if there is not enough time to reach the first goal of the sequence (if previous goal was 0xFFFFFFFF by example)

**Explanation:**

In this example, LED2CURRENTMAX = 0x0A3D (40 mA).

The LED2 output is controlled by writing on the LED2GOAL register.

LED2GOAL[00-15]: SPEED2 (% per milliseconde)

LED2GOAL[16-31]: LUM2 (%)

Goal luminosity is simply the ratio between the desired current and the max current:

$LUM2\_A = 5 / 40 = 12.5\% = 0x2000 (0.125 \times 65'536 = 8'192)$

$LUM2\_B = 20 / 40 = 50\% = 0x8000 (0.5 \times 65'536 = 32'768)$

Goal speed is an amount of percent per millisecond. In this case, we want 50%-12.5% = 37.5% in 2.5 seconds. The desired speed is therefore  $0.375 / 2.5s = 0.15 /s = 0.00015 /ms$ .

$SPEED2 = 0x000A = 10 (0.00015 \times 65'536 = 9.8304)$

**Note:**

The driver goes automatically in ultra-low power mode when all LEDs are turned-off. (e.g. If you write 0x0000FFFF in LEDxGOAL).

**(3) Monitor the driver**

Several parameters can be read during operation of the driver.

- You can verify that everything works well thanks to the WARNING register.
- You can read the input voltage thanks to VOLTAGE register.
- You can read the temperature of the board with the TEMPERATURE register.
- You can monitor the actual current sended to the output thanks to LEDxCURRENT registers (computed values).
- You can read values of the AD acquisition module.
- Etc.

**Analog to digital input**

The FMOD-I2C5LedDriver comes with 5 analog inputs. It allows conversion of an analog input signal to a corresponding 10-bit digital number. The result is stored and left justified on a 2 Bytes register: IOxAD

$IOxAD \text{ Max}$        $0xFFC0 = 65'472$   
 $IOxAD \text{ Min}$        $0x0000 = 0$   
 $IOxAD \text{ Step}$        $0x0040 = 64$

All AD measurement are refreshed 142 times per second (every 7ms)

### Example 1

A potentiometer is connected to the module as shown in Figure 4

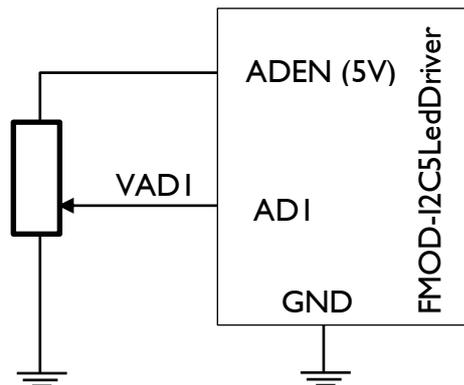

Figure 4 - Analog to digital module : example 1

- If  $IO/AD = 6'528$ , it means that  $VADI = 0.498V$  because  $(6'528 / 65'536) \times 5V = 0.498V$
- The slide pot is therefore at 10% of the range ( $0.498 / 5$ )

### Example 2

A temperature sensor is connected to the module as shown in Figure 5

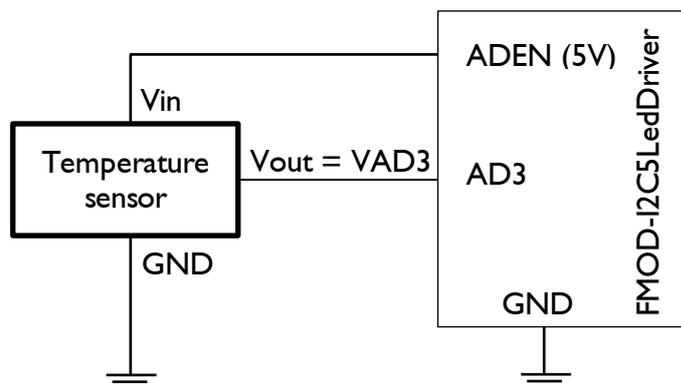

Figure 5 – Analog to digital module: example 2

**Sensor's characteristics:**  $V_{out} [mV] = (10 [mV/^{\circ}C] \times Temp [^{\circ}C]) + 500 [mV]$

- If  $IO3AD = 6'528$ , it means that  $VAD3 = 0.498V$ , because  $(6'528 / 65'536) \times 5V = 0.498 V$   
→ Temperature is therefore :  $(498-500) / 10 = -0.2^{\circ}C$
- If  $IO3AD = 49'152$ , it means that  $VAD3 = 0.75 V$ , because  $(49'152 / 65'536) \times 5V = 0.75 V$   
→ Temperature is therefore :  $(750-500) / 10 = 25^{\circ}C$

## 4. I2C Interface

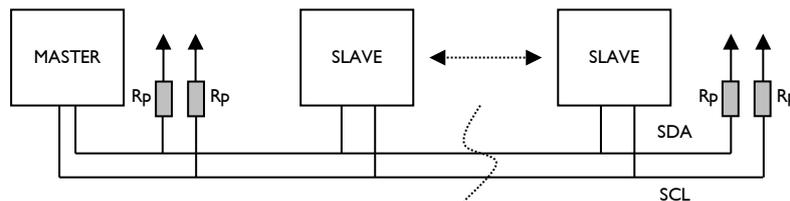

### Description

Registers are written to and read from the devices through the I2C bus; the controller is an I2C slave device. It is controlled by the I2C clock (SCL), which is driven by the I2C master. Data is transferred into and out of the cards through the I2C data (SDA) line. Either the slave or master device can pull the SDA line down; the I2C protocol determines which device is allowed to pull the SDA line down at any given time.

The maximum speed of the fast I2C interface is **400 kHz**.

#### WARNING:

A **pull up resistor  $R_p$**  (off-card) has to be placed between SDA and VCC (+5V) and between SCL and VCC. This is usually done at the beginning (near the master) and at the end (near the last device of the daisy chain) of the SDA and SCL lines.

( $R_p = 4.7k\Omega$ )

### Protocol

The I2C bus defines several different transmission codes, as follows:

- a start bit
- the slave device 8-bit address
- an (no) acknowledge bit
- an 8-bit message
- a stop bit

## Sequence

---

A typical read or write sequence begins by the master sending a start bit. After the start bit, the master sends the slave device's 8-bit address. The last bit of the address determines if the request will be a read or a write, where a '0' indicates a write and a '1' indicates a read. The slave device acknowledges its address by sending an acknowledge bit back to the master. If the request was a write, the master then transfers the 8-bit register address to which a write should take place. The slave sends an acknowledge bit to indicate that the register address has been received. The master then transfers the data 8 bits at a time, with the slave sending an acknowledge bit after each 8 bits.

The LED driver use data length of 1 byte up to 16 bytes for their internal registers. The master stops writing by sending a restart or stop bit.

A typical read sequence is executed as follows:

First the master sends the write-mode slave address and 8-bit register address just as in the write request. The master then sends a (re)start bit and the read-mode slave address. It clocks out the register data 8 bits at a time. The master sends an acknowledge bit after each 8-bit transfer. The data transfer is stopped when the master sends a no-acknowledge bit.

## Bus Idle State

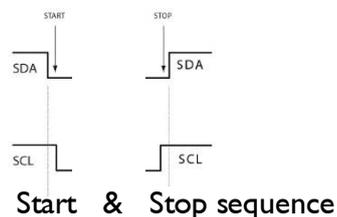

---

The bus is idle when both the data and clock lines are HIGH. Control of the bus is initiated with a Start bit, and the bus is released with a Stop bit. Only the master can generate the start and stop bits.

## Start Bit and Stop Bit

---

The start bit is defined as a HIGH to LOW transition of the data line while the clock line is HIGH. The stop bit is defined as a LOW to HIGH transition of the data line while the clock line is HIGH.

## I2C address selection

---

On each controller with I2C interface, its 7bits of I2C address must be defined in hardware. Each line needs to be connected to +5v logic (1) or logic ground (0). Do not leave any pin of address floating!

As example, if you want to set one FMod-I2C5LedDriver SLP to address 40 (0x28), convert 40 (decimal) in binary code (b'00101000'), the 7 least significant bits (→0101000) are the values to be set to the corresponding pins of J1 "I2C Address selection →6-0".

## Slave AddressWrite/Read

---

The 8-bit address of an I2C device consists of 7 bits of address and 1 bit of direction. A '0' in the LSB of the address indicates write-mode, and a '1' indicates read-mode.

If we want to do a **write-sequence** to the address 0x55, the AddressWrite is :

***AddressWrite = 0xAA*** [i2c address (0x55)<<1 + direction bit (0)]

and if we want to do a **read-sequence**, the address used is:

***AddressRead = 0xAB*** [i2c address (0x55)<<1 + direction bit (1)]

The **I2C address** of the device is the one that is hard-coded through the 7 address pins : [I2C Address selection bit 0,1,2,3,4,5,6,7 (in)]. With 7bits of address, 128 values are possible, but the first (8) ones (0x00-0x07) and last (8) ones (0x78-0x7F) are reserved for I2C protocol specific actions, these values must not be used as an I2C address. If the device is set with one wrong (reserved) address, it will take its default address 0x55 (85decimal, binary'1010101').

Therefore you can define the address you want between 0x08 to 0x77 (decimal 8-119).

## Data Bit Transfer

---

One data bit is transferred during each clock pulse. The I2C clock pulse is provided by the master. The data must be stable during the HIGH period of the I2C clock. It can change only when the I2C clock is LOW. Data is transferred 8 bits at a time, followed by an acknowledge bit.

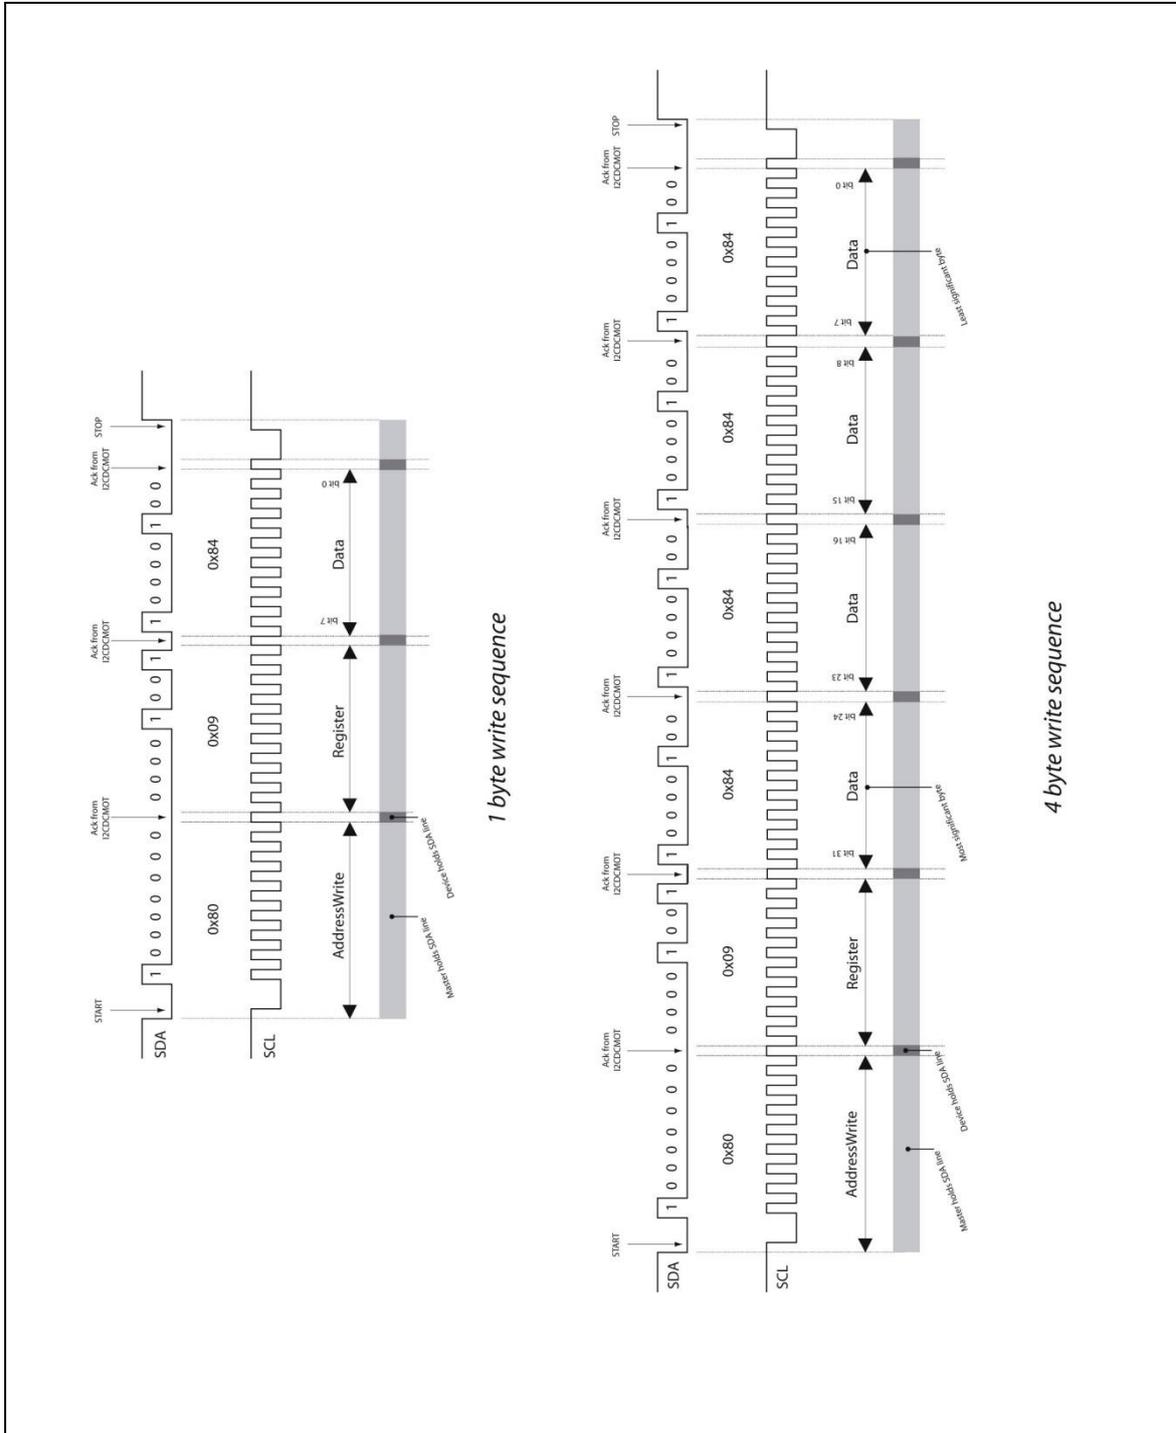

## Acknowledge and No-Acknowledge Bit

---

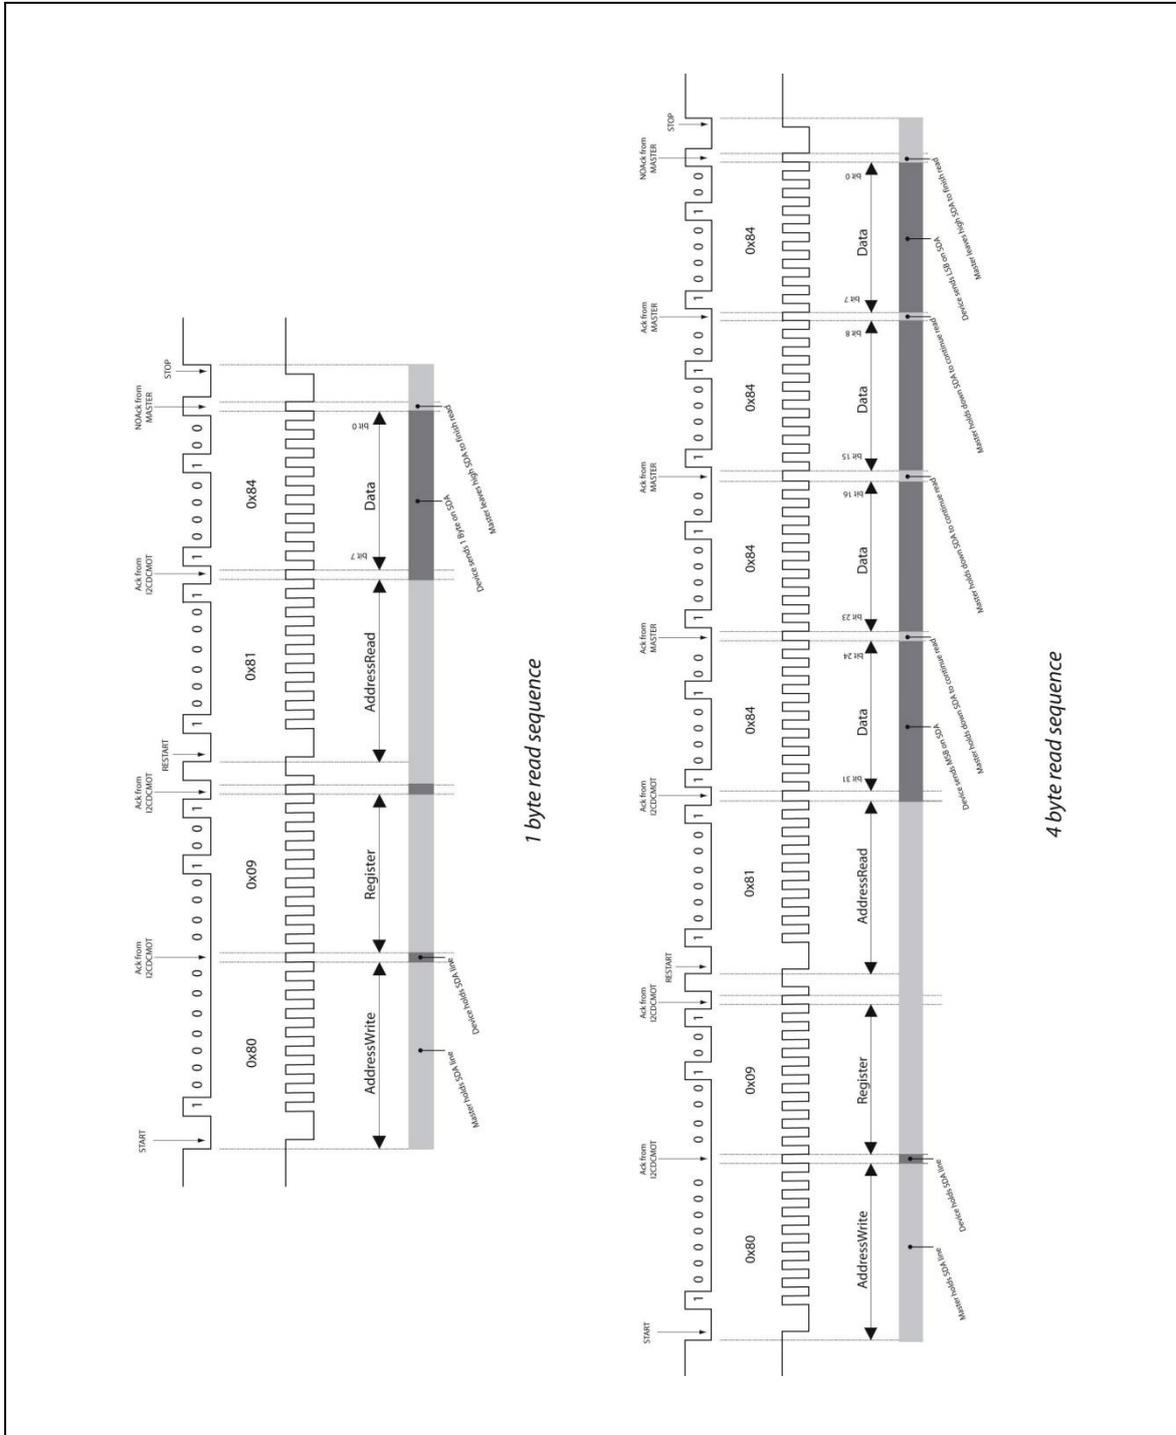

The master generates the acknowledge clock pulse. The transmitter (which is the master when writing, and the slave when reading) releases the data line, and the receiver indicates an acknowledge bit by pulling the data line low during the acknowledge clock pulse. The no-acknowledge bit is generated when the data line is not pulled down by the receiver during the

acknowledge clock pulse. A no-acknowledge bit is used to terminate a read sequence.

## Write Sequence (1 byte and 4 bytes)

## Read Sequence (1 byte and 4 bytes)

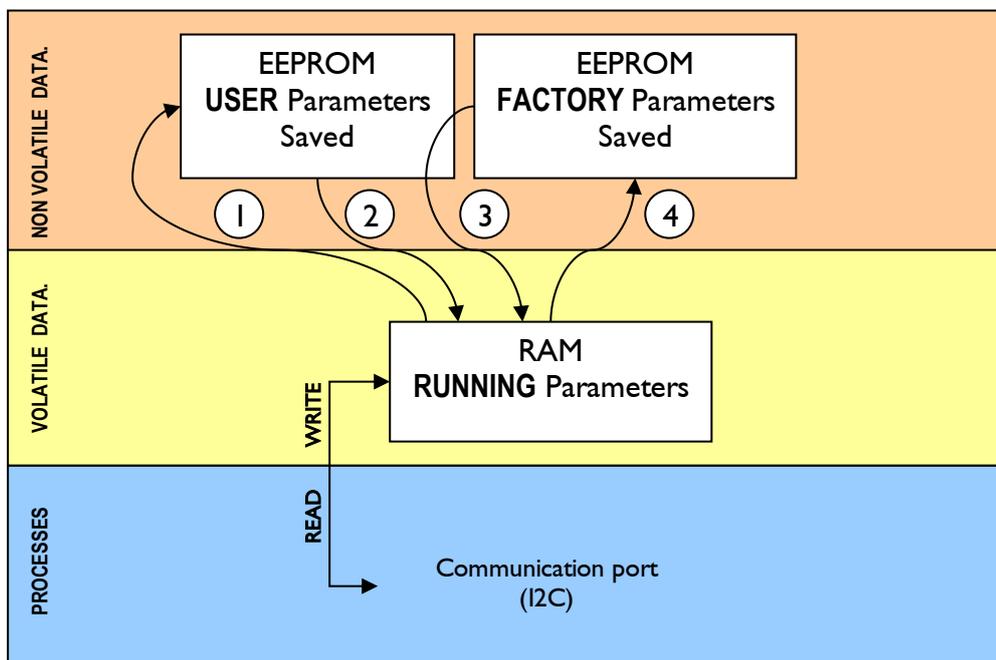

1 byte read sequence

4 byte read sequence

## 5. Register management

### Memory organization

The user needs to know that a new register value sent through the communication port is loaded to the running parameters in RAM and used for the current process. All these parameters are lost at power-down. It is necessary to save them to “User Parameters” or “Factory Parameters” with the corresponding function.

Action number and description:

- ① **SAVEUSERPARAMETERS** (0x03) function
- ② During standard power-up or calling **RESTOREUSERPARAMETERS** (0x04) function
- ③ **RESTOREFACTORYPARAMETERS** (0x05) function
- ④ + ① **SAVEFACTORYPARAMETERS** (0x06) function [for integrator engineers only]

## Full description of registers

## TYPE

Register Address	Register Name	Function	Read/Write control
0x00	TYPE	Product ID	Read only

Register Size	Register structure	
4 Bytes	Unsigned Int 16 bits (HH-HL) TYPE	Unsigned Int 16 bits (LH-LL) MODEL

**Description:**

Product identifier composed of a *Type* and *Model* number.

Defines the type of peripheral.

Normally different *TYPE* modules are not software compatible.

**Example:**

Device with *TYPE* = 0x002A0001 means *Type*=2A (42 = I2C Led Driver),  
*Model* = 1.

**Limits:**

None

**Active:**

Each time the processor is running.

## VERSION

---

Register Address	Register Name	Function	Read/Write control
0x01	VERSION	Software ID	Read only

Register Size	Register structure	
4 Bytes	2bytes Hardware version (HH-HL)	2 bytes Firmware version (LH-LL)

### Description:

Hardware identifier composed of a *Version* and *Revision* number.

Firmware identifier composed of a *Version* and *Revision* number.

Normally same *Version* with different *Revision* is backward compatible.

### Example:

VERSION 0x0108050E

Hardware = 0x0108 = Version 1.8

Firmware = 0x050E = Version 5.14

Firmware 5.14 = *Version* 5, *Revision* 14 (0x0E) is compatible with all earlier revisions of the same version (ver 5.0 to 5.14) but has new functionalities (deactivated by default) or code optimizations.

### Limits:

None

### Active:

Each time the processor is running.

**RESET CPU**

---

Function Address	Function Name	Function	Read/Write control
0x02	<i>RESETCPU</i>	Restart processor	Write only

Register Size	Register structure	Unit
0 Byte	none	none

**Description:**

Reboots the card. Communication will be lost.

**Active:**

Each time the processor is running.

## SAVE USER PARAMETERS

---

Function Address	Function Name	Function	Read/Write control
0x03	SAVEUSERPARAMETERS	Saves all in EEPROM	Write only

Register Size	Register structure	Unit
0 Byte	none	none

### Description:

Saves the following parameters to EEPROM user space:

0x10 *COMOPTIONS*  
 0x12 *I2CADDRESS*  
 0x15 *DEVICENAME*  
  
 0x21 *OPTIONS*  
 0x22 *DRVVOLTAGEMIN*  
  
 0x30 *LED1CURRENTMAX*  
 0x31 *LED2CURRENTMAX*  
 0x32 *LED3CURRENTMAX*  
 0x33 *LED4CURRENTMAX*  
 0x34 *LED5CURRENTMAX*

### Active:

Each time the processor is running.

Do not change any of these parameters while saving!

## RESTORE USER PARAMETERS

---

Function Address	Function Name	Function	Read/Write control
0x04	RESTOREUSERPARAMETERS	Restores saved values	Write only

Register Size	Register Structure	Unit
0 Byte	none	none

**Description:**

Restores the user parameters from EEPROM.

See *SAVEUSERPARAMETERS* (0x03) register list.

**Active:**

Each time the processor is running.

## RESTORE FACTORY PARAMETERS

---

Function Address	Function Name	Function	Read/Write control
0x05	RESTOREFACTORYPARAMETERS	Factory default	Write only

Register Size	Register Structure	Unit
0 Byte	none	none

**Description:**

Restores factory parameters.

See *SAVEUSERPARAMETERS* (0x03) register list.

**Active:**

Each time the processor is running, *SAVEUSERPARAMETERS* has to be run after setting this function so that the next reboot will retain the same parameters.

## SAVE FACTORY PARAMETERS

---

Function Address	Function Name	Function	Read/Write control
0x06	SAVEFACTORYPARAMETERS	Saves factory default	Write only

Register Size	Register Structure	Unit
0 Byte	none	none

### **Description:**

This function is reserved for integrator engineers, and not for the end user. Used when all parameters have been approved for an application. It saves in EEPROM all configurable registers for both factory parameters and user parameters.

This function also call the *SAVEUSERPARAMETERS* function.

See *SAVEUSERPARAMETERS* (0x03) register list.

### **Active:**

Each time the processor is running.

Do not change any of these parameters while saving!

## VOLTAGE

---

Register Address	Register Name	Function	Read/Write Control
0x07	VOLTAGE	Power module voltage	Read only

Register Size	Register Structure	Unit
4 Bytes	Signed (2's cplt) Int 16 (HH-HL) + 16 bits fixed point (LH-LL)	Volt

### Description:

Input voltage

### Limits:

Max      0x7FFFFFFF<sub>xx</sub> = 32'767.996

Min      0x000000<sub>xx</sub> = 0.0

Step     0x000001<sub>xx</sub> = 0.004

### Example:

When read 0x00234567 = 2'311'527, Voltage = 35.27 (2'311'527/65'536)

### Active:

Each time the processor is running.

**WARNING**

Register address	Register Name	Function	Read/Write Control
0x08	WARNING	Bit to bit state	R/W

Register Size	Register Structure	Unit
4 Bytes	Unsigned Int 32 bits , each bit independent	none

**Description:**

Each information/warning/error is made up of 2 bits: the first one shows the current state, the next one shows whether this state has appeared previously.

Only the bits that show the past states can be cleared by writing 0x00000000 to the *WARNING* register.

**Bits when set**

*Warnings.0* Under-voltage of the power input.

*Warnings.1* Previously active, it can be cleared by user.

*Warnings.2* Over-voltage of the power input.

*Warnings.3* Previously active, it can be cleared by user.

*Warnings.4* Over-temperature state, reduce the output current to 75% of its value when temperature > 115°C, 50% when > 120°C, 25% when > 125°C, 0% when > 130°C.

*Warnings.5* Previously active, it can be cleared by user.

*Warnings. 6-31* Reserved

**Default: bits 31 -> 0**

0x00 00 00 00

**Active:**

Each time the processor is running.

## NB POWER UP

---

Register address	Register Name	Function	Read/Write Control
0x0B (11)	<i>NBPOWERUP</i>	Number of power up in device's life	Read only

Register Size	Register Structure	Unit
4 Bytes	Unsigned Int 32 bits	none

### **Description:**

The number of power up is incremented each time the controller's power supply and the logic 5V are in the specifications range.

### **Limits:**

Min        0x00 00 00 00 = 0

Max        0xFF FF FF FF = 4'294'967'295

### **Active:**

Each time the processor is running

## TIME IN SERVICE

---

Register address	Register Name	Function	Read/Write Control
0x0C	<i>TIMEINSERVICE</i>	Time in service in device's life	Read only

Register Size	Register Structure	Unit
4 Bytes	Unsigned Int 32 bits	Seconds

### **Description:**

The *TIMEINSERVICE* register is incremented every second when the driver is not in Standby

### **Limits:**

Min        0x00 00 00 00 = 0 seconds

Max        0xFF FF FF FF = 4'294'967'295 seconds = ~136 years

### **Active:**

Each time the processor is running.

## COM OPTIONS

---

Register Address	Register Name	Function	Read/Write Control
0x10 (16)	COMOPTIONS	Communication options	Read/Write

Register Size	Register Structure	Unit
4 Bytes	32 individual bits	none

**Description:**

This register is reserved for future use.

This register is saved when calling the function *SAVEUSERPARAMETERS* or *SAVEFACTORYPARAMETERS*.

## I2C ADDRESS

---

Register Address	Register Name	Function	Read/Write Control
0x12 (18)	I2CADDRESS	Network ID	Read(/Write)

Register Size	Register Structure	Unit
4 Bytes	4 x Unsigned Bytes	none

### **Description:**

Network identifier of 7bits used for I2C bus, without R/W bit.

Only the least significant byte is used for the address. Value can be [8-119], [0x08-0x77].

Since the value is Hardware coded (I<sup>2</sup>C address lines 0-7), writing in this register will not affect the effective I<sup>2</sup>C address.

### **Limits of I2C ID:**

Min = 0x08 (8)

Max = 0x77 (119)

Because b'0000xxx' and b'1111xxx' are reserved for I2C specific actions.

If a wrong ID is coded, the device will automatically use its default value 0x55.

## DEVICE NAME

---

Register Address	Register Name	Function	Read/Write Control
0x15 (21)	DEVICENAME	Device's ASCII name	Read/Write

Register Size	Register Structure	Unit
16 Bytes	16 (only) x Unsigned Bytes (CHAR)	none

### Description:

Name and/or description of the device.

This register is saved when calling the function *SAVEUSERPARAMETERS* or *SAVEFACTORYPARAMETERS*.

### Example:

For the name "Hello Module"; extend to 16 Bytes the name: "Hello Module"+5x space=16 Byte.

So write 0x48656C6C 6F204D6F 64756C65 20202020.

## OPTIONS

---

Register Address	Register Name	Function	Read/Write Control
0x21 (33)	OPTIONS	Bit to bit settings	Write (Read)

Register Size	Register Structure	Unit
4 Byte	Unsigned Int 32 bits , each bit independent	none

### Description:

This register is saved when calling the function *SAVEUSERPARAMETERS* or *SAVEFACTORYPARAMETERS*.

**Bits**                      *when set*  
*OPTIONS.0*                Enable the low power PWM mode. Usefull when available logical power is limited. The CPU speed is slowed by a factor of 4 reducing therefore power consumption (on logical 5V power). Counterpart is that the PWM frequency is also divided by 4 and induces therefore 4 times higher ripple on LED current output. Except for very special cases, this bit must stay cleared.

*OPTIONS.1-31* Reserved

### Limits:

None

### Default:

bits 31 -> 0 : 0x00, 0x00, 0x00 , b'00000001'

### Active:

Each time the processor is running.

## DRIVER VOLTAGE MIN

---

Register Address	Register Name	Function	Read/Write Control
0x22 (34)	DRVOLTAGEMIN	Voltage threshold	Write only

Register Size	Register Structure	Unit
4 Bytes	Signed (2's cplt) Int 16 (HH-HL) +16 bits fixed point (LH-LL)	Volt

### Description:

Minimal input voltage

### Information:

When *VOLTAGE* is smaller than *DRVOLTAGEMIN* or 5.5V the LEDs driver is switched off.

### Limits:

Max  $0x7FFFFFFx = 32'767.996$

Min  $0x000000xx = 0.0$

Step  $0x000001xx = 0.004$

### Example:

When read  $0x00234567 = 2'311'527$ , Value =  $35.27 (2'311'527/65'536)$

### Default:

$0x00058000 = 360'448$ , Value =  $5.5 \text{ V} (360'448/65536)$

### Active:

Each time the processor is running.

## TEMPERATURE

---

Register Address	Register Name	Function	Read/Write Control
0x23 (35)	TEMPERATURE	Board °C	Read only

Register Size	Register Structure	Unit
4 Bytes	Signed (2's cplt) Int 16 (HH-HL) + 16 bits fixed point (LH-LL)	°C

### Description:

It gives temperature of the board.

This value is used inside the device to reduce the current output at the power bridge to prevent overheating destruction.

$0 < T^{\circ} < \sim 90^{\circ}\text{C}$	Normal temperature
$90^{\circ}\text{C} < T^{\circ} < 115^{\circ}\text{C}$	Critical temperature, but functioning
$115^{\circ}\text{C} < T^{\circ} < 120^{\circ}\text{C}$	Over-temperature state, reduce the output current to 75% of its value
$120^{\circ}\text{C} < T^{\circ} < 125^{\circ}\text{C}$	Reduce the output current to 50% of its value
$125^{\circ}\text{C} < T^{\circ} < 130^{\circ}\text{C}$	Reduce the output current to 25% of its value
$130^{\circ}\text{C} < T^{\circ}$	Reduce the output current to 0% of its value

Automatic re-enabling of the power bridge to the maximum value when  $T^{\circ} < 113^{\circ}\text{C}$ .

### Limits:

Max	0x00960000 = 150°C
Min	0xFFD80000 = -40.0 °C

### Example:

Other     0x00168000 = 1474560 → 22.5°C = (1474560/65536)

### Active:

Each time the processor is running.

## I/O STATE

---

Register Address	Register Name	Function	Read/Write Control
0x24 (36)	<i>IOSTATE</i>	A/D measurements	Read only

Register Size	Register Structure	Unit
10 Bytes (5 x 2 Bytes)	Unsigned Int 16 bits Unsigned Int 16 bits Unsigned Int 16 bits Unsigned Int 16 bits Unsigned Int 16 bits	None

### **Description:**

Result of the analog to digital conversion of all ADx input in a 10 Bytes register.

IOSTATE.[00-15] : A/D acquisition of I/O 1

IOSTATE.[16-31] : A/D acquisition of I/O 2

IOSTATE.[32-47] : A/D acquisition of I/O 3

IOSTATE.[48-63] : A/D acquisition of I/O 4

IOSTATE.[64-79] : A/D acquisition of I/O 5

For more convenience, you can also get each A/D acquisition individually by using the IOxAD registers.

### **Limits:**

The resolution of each AD acquisition is a 10-bit digital number. The result is left justified on 2 Bytes for each conversion.

IOSTATE.[00-15], IOSTATE.[16-31], IOSTATE.[32-47], IOSTATE.[48-63], IOSTATE.[64-79]

Max        0xFFC0 = 65'472

Min        0x0000 = 0

Step       0x0040 = 64

### **Active:**

Each time the processor is running.

## LEDxCURRENTMAX

Registers Addresses	Registers Names	Function	Read/Write Control
0x30(48) 0x31(49) 0x32(50) 0x33(51) 0x34(52)	LED1CURRENTMAX LED2CURRENTMAX LED3CURRENTMAX LED4CURRENTMAX LED5CURRENTMAX	Defines max current	Write (Read)

Register Size	Register Structure	Unit
2 Bytes	16 bits fixed point (H-L)	Ampere
2 Bytes	16 bits fixed point (H-L)	
2 Bytes	16 bits fixed point (H-L)	
2 Bytes	16 bits fixed point (H-L)	
2 Bytes	16 bits fixed point (H-L)	

### Description:

This register defines the maximal output current of LEDx when LUMx is set to 100%.

This register is saved when calling the function SAVEUSERPARAMETERS or SAVEFACTORYPARAMETERS.

### Information:

The conversion factor between LUMx and LEDICURRENT depends on the LEDICURRENTMAX register.

### Example:

$$\begin{aligned} LUM1 &= 0x8000 : 50\% (32'768/65'536) \\ LED1CURRENTMAX &= 0x4000 : 250mA (16'384/65'536) \end{aligned}$$

$$\Rightarrow LED1CURRENT = 0x2000 : 125 \text{ mA} (8'192/65'536)$$

### Limits:

$$\begin{aligned} \text{Max} & 0x8000 = 32'768 : 500 \text{ mA} (32'768/65'536) \\ \text{Min} & 0x0000 : 0.0 \text{ mA} \\ \text{Step} & 0x0001 : 0.0153 \text{ mA} (1/65'536) \end{aligned}$$

LEDICURRENTMAX is internally limited to 0x8000 (500mA) if the user try to write a higher value.

### Default:

$$0x8000 = 32'768 : \text{Current max} = 500 \text{ mA} (32'768/65'536)$$

### Active:

Each time the processor is running.

## LEDxCURRENT

---

Register Address	Register Name	Function	Read/Write Control
0x35 (53) 0x36 (54) 0x37 (55) 0x38 (56) 0x39 (57)	<i>LED1CURRENT</i> <i>LED2CURRENT</i> <i>LED3CURRENT</i> <i>LED4CURRENT</i> <i>LED5CURRENT</i>	Current	Read only

Register Size	Register Structure	Unit
2 Bytes 2 Bytes 2 Bytes 2 Bytes 2 Bytes	16 bits fixed point (H-L) 16 bits fixed point (H-L) 16 bits fixed point (H-L) 16 bits fixed point (H-L) 16 bits fixed point (H-L)	Ampere

### Description:

This register informs the user of the actual current sent to the LEDx output

### Limits:

Max        0x8000 = 32'768 : 500 mA (32'768/65'536)  
 Min        0x0000 : 0.0 mA  
 Step       0x0001 : 0.0153 mA (1/65'536)

### Active:

Each time the processor is running

## LEDxGOAL

---

Register Address	Register Name	Function	Read/Write Control
0x3A (58) 0x3B (59) 0x3C (60) 0x3D (61) 0x3E (62)	LED1GOAL LED2GOAL LED3GOAL LED4GOAL LED5GOAL	Set LEDx goal	Write (Read)

Register Size	Register Structure	Unit
4 Byte	Int 16 + Int 16	none

### Description:

This register is used by the user to control the driver. The 2 high Bytes set the luminosity goal (in percent). The 2 low Bytes set the speed to reach the goal (in percent per millisecond).

LUMx and SPEEDx :

LED1GOAL.[00-15] : SPEED1 (% per millisecond)  
LED1GOAL.[16-31] : LUM1 (%)

LED2GOAL.[00-15] : SPEED2 (% per millisecond)  
LED2GOAL.[16-31] : LUM2 (%)

LED3GOAL.[00-15] : SPEED3 (% per millisecond)  
LED3GOAL.[16-31] : LUM3 (%)

LED4GOAL.[00-15] : SPEED4 (% per millisecond)  
LED4GOAL.[16-31] : LUM4 (%)

LED5GOAL.[00-15] : SPEED5 (% per millisecond)  
LED5GOAL.[16-31] : LUM5 (%)

### Limits:

#### SPEEDx

Max      0xFFFF : 100% per millisecond (65'535/65'536)  
Min      0x0000 : 0.0 % per millisecond  
Step     0x0001 : 0.0015259 % per millisecond

#### LUMx

Max      0xFFFF : 100% (65'535/65'536)  
Min      0x0000 : 0.0 %  
Step     0x0001 : 0.0015259 % (1/65'536)

**Default:**

0x0000FFFF :  $LUM_x = 0\%$ ,  $SPEED_x = 100\%$  per second

**Example**

<i>LEDICURRENTMAX</i>	=	0x4000 : 250mA (16'384/65'536)
<i>LEDIGOAL</i>	=	0x2000010
		0x8000 : 50 % (32'768/65'536)
		0x0010 : 24.41 % per second (16/65536)

⇒ *LEDICURRENT* : From 0x0000 to 0x8000 : 0 to 125 mA (8'192/65'536) in 2,048 seconds

**Active:**

Each time the processor is running.

## AUTO TEST LEDES

Register Address	Register Name	Function	Read/Write Control
0x3F (63)	AUTOTESTLEDS	Test 5 LED outputs	Write

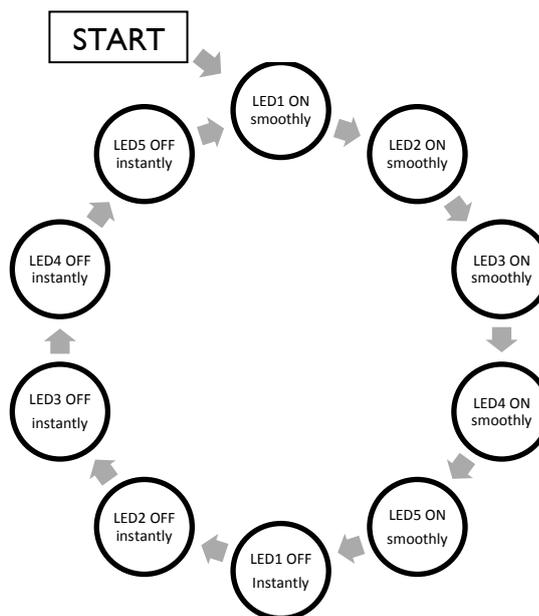

Register Size	Register Structure	Unit
0 Byte	none	none

### Description:

This function helps the user to test quickly LED outputs.

### Information

The function sets LEDxGOAL each time it is called with respect to the following diagram:

LEDx ON means LEDxGOAL = 0xFFFF0005

LEDx OFF means LEDxGOAL = 0x0000FFFF

### Beware:

The LEDxCURRENTMAX

registers must be configured appropriately since AUTOTESTLEDS sends maximum current to each LED output.

### Active:

Each time the processor is running.

**IOxAD**

Register Address	Register Name	Function	Read/Write Control
0x40 (64)	<i>IO1AD</i>	A/D measurements	Read
0x41 (65)	<i>IO2AD</i>		
0x42 (66)	<i>IO3AD</i>		
0x43 (67)	<i>IO4AD</i>		
0x44 (68)	<i>IO5AD</i>		

Register Size	Register Structure	Unit
2 Byte	Unsigned Int 16 bits	none
2 Byte	Unsigned Int 16 bits	
2 Byte	Unsigned Int 16 bits	
2 Byte	Unsigned Int 16 bits	
2 Byte	Unsigned Int 16 bits	

**Description:**

Result of the analog to digital conversion of ADx input.

If synchronisation between the 5 A/D acquisitions is critical, use IOSTATE register instead since it guarantees that all acquisitions you read were done simultaneously (in a time window of 7ms).

**Limits:**

The resolution of each AD acquisition is a 10-bit digital number. The result is left justified on 2 Bytes for each ADx input

Max        0xFFC0 = 65'472  
 Min        0x0000 = 0  
 Step       0x0040 = 64

**Active:**

Each time the processor is running.
